Abstract
Subgraph enumeration is a fundamental task in computer science. Since the number of subgraphs can be large, some enumeration algorithms exploit compressed representations for efficiency. One such representation is the Zero-suppressed Binary Decision Diagram (ZDD). ZDDs can represent the set of subgraphs compactly and support several poly-time queries, such as counting and random sampling. Researchers have proposed efficient algorithms to construct ZDDs representing the set of subgraphs under several constraints, which yield fruitful results in many applications. Recently, Zero-suppressed Sentential Decision Diagrams (ZSDDs) have been proposed as variants of ZDDs. ZSDDs can be smaller than ZDDs when representing the same set of subgraphs. However, efficient algorithms to construct ZSDDs are known only for specific types of subgraphs: matchings and paths.

We propose a novel framework to construct ZSDDs representing sets of subgraphs under given constraints. Using our framework, we can construct ZSDDs representing several sets of subgraphs such as matchings, paths, cycles, and spanning trees. We show the bound of sizes of constructed ZSDDs by the branch-width of the input graph, which is smaller than that of ZDDs by the path-width. Experiments show that our methods can construct ZSDDs faster than ZDDs and that the constructed ZSDDs are smaller than ZDDs when representing the same set of subgraphs.

1 Introduction
Enumerating subgraphs of a given graph under some constraint is a fundamental task in computer science. There are enumeration algorithms for several types of subgraphs such as cliques [5], paths [1], and spanning trees [21]. These algorithms list all subgraphs one by one in a small amount of time per subgraph. However, such algorithms take at least linear time and space to the number of subgraphs. Since the number of subgraphs can be exponentially larger than the size of the input graph, it is trouble when applied to practical problems.
Instead of explicitly listing subgraphs, some algorithms exploit compressed representations of sets of subgraphs. One such representation is the Zero-suppressed Binary Decision Diagram (ZDD) [15]. ZDDs are compact representations of set families. By regarding a subgraph as its edge set, we can express a set of subgraphs by a ZDD. ZDDs can not only represent set families compactly but also support several poly-time queries such as counting and random sampling [15]. In addition, given two ZDDs, we can efficiently construct a ZDD representing the union or intersection of the set families represented by the input ZDDs in polynomial time to the sizes of the input ZDDs. Such operations are called Apply operations [4]. Due to these merits, ZDDs appear in several graph-related applications such as network optimization [10], network reliability evaluation [7, 8], and balanced graph partitions [12, 16, 17].

A key to use ZDDs effectively for subgraph enumeration is a fast algorithm to construct a ZDD representing the set of subgraphs. It is time-consuming to construct a ZDD by first explicitly listing subgraphs and then combining ZDDs using Apply operations. In contrast, some algorithms can construct ZDDs without explicitly listing subgraphs. Such algorithms are called top-down construction algorithms, while algorithms using Apply operations are called bottom-up. Researchers have proposed top-down construction algorithms for ZDDs representing several sets of subgraphs [20, 7, 14]. Kawahara et al. [13] generalized the algorithms to obtain a general framework of top-down construction algorithms for ZDDs. Using the framework, we can construct ZDDs representing the sets of subgraphs under several constraints, such as the number of edges, degrees of vertices, and connectivity of vertices. By combining these fundamental constraints, we can specify several types of subgraphs, such as matchings, paths, cycles, and spanning trees.

Recently, Zero-suppressed Sentential Decision Diagrams (ZSDDs) [18] have been proposed as different representations of set families. Since ZSDDs are generalizations of ZDDs, ZSDDs are at least as compact as ZDDs. In theory, there exist set families that have polynomial ZSDD sizes but exponential ZDD sizes [3]. In addition, ZSDDs inherit some poly-time queries of ZDDs: counting, random sampling, and Apply operations. Thus, a natural question is: Can we design top-down construction algorithms for ZSDDs representing sets of subgraphs? The question is partially answered in an affirmative way by Nishino et al. [19]. They proposed top-down construction algorithms for ZSDDs representing sets of specific types of subgraphs: matchings and paths. The sizes of constructed ZSDDs by their algorithms are bounded by the branch-width of the input graph [19], while those of ZDDs are bounded by the path-width [11]. Since the branch-width of a graph never exceeds the path-width [2], ZSDDs have tighter upper bounds than ZDDs. The efficiency of their algorithms was confirmed in experiments. Despite such striking results, their algorithms are specific to matchings and paths.

In this paper, we propose a novel framework of top-down construction algorithms for ZSDDs. To design a top-down construction algorithm using our framework, one only has to prove a recursive formula for the desired set of subgraphs. Using the recursive formula, we can theoretically show the correctness and the complexity of the algorithm, which was difficult with the existing method. We apply our framework to the three fundamental constraints used in ZDDs: the number of edges, degrees of vertices, and connectivity of vertices. We show that the sizes of constructed ZSDDs are bounded by the branch-width of the input graph, not only for matchings and paths. Experiments show that proposed methods can construct ZSDDs faster than ZDDs and that the constructed ZSDDs are smaller than ZDDs representing the same sets of subgraphs.
2 Preliminaries

2.1 Graphs

Let $G = (V, E)$ be an undirected graph where $V$ is the vertex set and $E$ is the edge set. $|V|$ and $|E|$ denote the number of vertices and edges, respectively. For edge subset $S \subseteq E$, the induced subgraph $G[S]$ is the subgraph $(V[S], S)$, where $V[S] \subseteq V$ is the set of vertices to which an edge in $S$ is incident. In the following, we identify $S$ with $G[S]$.

For $S \subseteq E$ and $u \in V$, the degree $\deg(S, u)$ of $u$ in $S$ is the number of edges incident to $u$ in $S$.

2.2 $(X, Y)$-partition and vtree

Let $f$ and $g$ be set families. We define three operations between set families. We define union $\cup$, intersection $\cap$, and join $\sqcup$ as $f \cup g = \{a \mid a \in f \text{ or } a \in g\}$, $f \cap g = \{a \mid a \in f \text{ and } a \in g\}$, and $f \sqcup g = \{a \cup b \mid a \in f \text{ and } b \in g\}$, respectively.

Definition 1. Let $f$ be a set family, and $X, Y$ be a partition of the universe of $f$. Set family $f$ can be written as

$$f = \bigcup_{i=1}^{h} [p_i \sqcup s_i],$$

where $p_i$ and $s_i$ are the set families whose universes are $X$ and $Y$, respectively. The equation is an $(X, Y)$-decomposition. We call $p_1, \ldots, p_h$ primes and $s_1, \ldots, s_h$ subs. If the primes are exclusive ($p_i \cap p_j = \emptyset$ for all $i \neq j$), the decomposition is an $(X, Y)$-partition.  

Example 2. Let $f_1$ be the family of subsets of $U_1 = \{A, B, C, D\}$ that contain exactly two elements. It follows that $f_1 = \{\{A, B\}, \{A, C\}, \{A, D\}, \{B, C\}, \{B, D\}, \{C, D\}\}$. For $X_1 = \{B\}$ and $Y_1 = \{A, C, D\}$, an $(X_1, Y_1)$-partition of $f_1$ is

$$f_1 = [\{\emptyset\} \cup \bigcup_{\text{prime}} f_1^1 \cup \bigcup_{\text{sub}} \bigcup_{\text{prime}} f_1^2],$$

where $f_1^1 = \{\{A, C\}, \{A, D\}, \{C, D\}\}$ and $f_1^2 = \{\{A\}, \{C\}, \{D\}\}$.

In [18], an $(X, Y)$-decomposition is called an $(X, Y)$-partition if the primes are exclusive and consistent ($p_i \neq \emptyset$ for all $i$). For simplicity, we do not require consistency for $(X, Y)$-partitions. If we construct a ZSDD without consistency, we can make their primes consistent in linear time to the ZSDD size [19].

![Figure 1](image-url) A vtree and a ZSDD that respects the vtree.
The universe of $f^1_2$ and $f^2_2$ is $U_2 = \{A, C, D\}$. For $X_2 = \{A, D\}$ and $Y_2 = \{C\}$, an $(X_2, Y_2)$-partition of $f^2_2$ is

$$f^2_2 = \left[\left(\{\{A, D\}\} \cup \emptyset\right) \cup \left(\{\{A\}, \{D\}\} \cup \{\{C\}\}\right)\right].$$  \hfill (3)

A ZSDD represents a set family by recursively applying $(X, Y)$-partitions to decompose the family into sub-families, where the order of partitions is determined by a vtree. A vtree is a rooted, ordered, and full binary tree whose leaves correspond to elements of the universe. Figure 1a shows an example. Symbols appearing in leaves represent corresponding elements, and symbols beside nodes represent their names. Each internal node represents a partition of the universe into two subsets: elements appearing in the left and right subtrees. We denote the left and right children of node $v$ by $v^l$ and $v^r$, respectively. In the figure, root node $v_1$ represents the $(X_1, Y_1)$-partition of the universe $U_1 = \{A, B, C, D\}$ where $X_1 = \{B\}$ and $Y_1 = \{A, C, D\}$. Similarly, node $v_2$ represents the $(X_2, Y_2)$-partition of the universe $U_2 = \{A, C, D\}$ where $X_2 = \{A, D\}$ and $Y_2 = \{C\}$. To avoid confusion, we call vtree nodes vnodes, ZSDD nodes znodes, and graph nodes vertices. We represent them as $v_1$, $z_1$, and $u_i$.

### 2.3 Zero-suppressed Sentential Decision Diagrams

A ZSDD is recursively defined as follows. ZSDD α respects vnode $v$ if the order of $(X, Y)$-partitions in α follows the vtree whose root is $v$. (α) denotes the set family that α represents.

**Definition 3.** α is a ZSDD that respects vnode $v$ if and only if:

- $\alpha = \epsilon$ or $\alpha = \bot$. (Semantics: $\langle \epsilon \rangle = \emptyset$ and $\langle \bot \rangle = \emptyset$.)
- $\alpha = X$ or $\alpha = \pm X$ and $v$ is a leaf with element $X$. (Semantics: $\langle X \rangle = \{\{X\}\}$ and $\langle \pm X \rangle = \{\{X\},\emptyset\}$.)
- $\alpha = \{\{p_1, s_1\}, \ldots, \{p_h, s_h\}\}$, $v$ is internal, $p_1, \ldots, p_h$ are ZSDDs that respect a vnode in the subtree whose root is $v^l$, $s_1, \ldots, s_h$ are ZSDDs that respect a vnode in the subtree whose root is $v^r$, and $\{p_1\}, \ldots, \{p_h\}$ are exclusive. (Semantics: $\langle \alpha \rangle = \bigcup_{i=1}^{h}\{\{p_i\} \cup \{s_i\}\}$.)

If a ZSDD is either $\epsilon, \bot, X$, or $\pm X$, it is a terminal. Otherwise, it is a decomposition. Figure 1b shows an example ZSDD that represents set family $f_1$ in Example 2 and respects the vtree in Figure 1a. A circle node and its child rectangle nodes represent an $(X, Y)$-partition. The symbol in a circle node indicates the vnode that the decomposition respects. A pair of rectangle nodes represent a prime-sub pair in an $(X, Y)$-partition where the left and right are prime $p$ and sub $s$, respectively. Every $p$ and $s$ is either a terminal ZSDD or a pointer to a decomposition ZSDD. Circle nodes are decomposition znodes, and rectangle nodes are element znodes. For example, znodes $z_1$ and $z_2$ represent the $(X, Y)$-partitions in Equations (2) and (3), respectively. The size of a ZSDD is the sum of the sizes of $(X, Y)$-partitions in the ZSDD. The size of the ZSDD in Figure 1b is 9.  

### 3 A novel framework of top-down ZSDD construction

We present a novel framework of top-down ZSDD construction. Our framework is partially identical to that of Nishino et al.’s [19], but we modify it so that we can design algorithms easily for several constraints. Algorithm 1 shows the framework. The algorithm takes graph $G$ and the root vnode as its inputs and returns a ZSDD representing a set of subgraphs.

---

2 The size of a ZDD is defined as the number of nodes. [15] This is because, every node of a ZDD has exactly two children. In contrast, nodes of a ZSDD may have different number of children, and thus the size of a ZSDD is defined as the number of arcs.
We explain how to design labels in Section 4. The constructed ZSDD may have redundant vnode. In [19], the procedure of internal vnode, we call elems set the prime-sub pair znode that respects such a znode exists, the function returns its address. Otherwise, the function creates a new vnode and returns vnode types of subgraphs. If leaf vnode^{-}\in\{l, r\} and returns the set of pairs of labels corresponding to the prime-sub pairs (Line 3). For each the empty set (Line 2). Function reduce (znode corresponding to vnode) so that two znodes are equivalent if they respect the same vnode and have the same label. To detect equivalent znodes efficiently, we attach the construction of a ZSDD. Here, two znodes are equivalent if they respect the same vnode and have the same label. Instead, we treat all internal vnodes in the same way, which makes it easy to design algorithms for several constraints. For each znode z in Z[v], the function calculates the prime-sub pairs corresponding to z. We first initialize the set of prime-sub pairs elems to the empty set (Line 2). Function decomp(v, z) receives vnode v and znode z that respects v, and returns the set of pairs of labels corresponding to the prime-sub pairs (Line 3). For each o \in \{l, r\}, if v^o is a leaf vnode, we set vnode z^o to a terminal (Line 5). Function terminal(v, m) receives leaf vnode v and label m, and returns an appropriate terminal depending on the types of subgraphs. If v^o is an internal vnode, we call unique(v, m, Z) (Line 6). The function receives vnode v and label m, and checks whether Z[v] contains a znode with label m. If such a znode exists, the function returns its address. Otherwise, the function creates a new vnode that respects v and has label m, stores it into Z[v], and returns its address. We add the prime-sub pair (z^o, z^r) into elems (Line 7). After generating all the prime-sub pairs, we set elems as the child znodes of z (Line 8). Finally, for each o \in \{l, r\} such that v^o is an internal vnode, we call construct(v^o, Z) to recursively construct sub-ZSDDs (Lines 9–10).

Algorithm 1 A top-down construction algorithm.

Input : A graph \( G = (V, E) \) and the root vtree node \( v \)
Output : A ZSDD representing a set of subgraphs of \( G \)
1 \( Z[v] \leftarrow \text{rootState}() \)
2 construct(v, Z)
3 \( Z \leftarrow \text{reduce}(Z) \)
4 return \( Z \)

Algorithm 2 construct(v, Z).

1 for \( z \in Z[v] \) do
2 \hspace{1em}_elems \leftarrow \emptyset
3 \hspace{2em} for \( (m', m) \in \text{decomp}(v, z) \) do
4 \hspace{3em} for o \in \{l, r\} do
5 \hspace{4em} if v^o is a leaf vnode then \( z^o \leftarrow \text{terminal}(v^o, m^o) \)
6 \hspace{4em} else \( z^o \leftarrow \text{unique}(v^o, m^o, Z) \)
7 \hspace{3em} elems \leftarrow \text{elems} \cup \{(z', z^o)\}
8 \hspace{2em} Set \text{elems} as the child znodes of \( z \)
9 \hspace{1em} for o \in \{l, r\} do
10 \hspace{2em} if v^o is an internal vnode then construct(v^o, Z)

of \( G \). \( Z[v] \) stores a set of decomposition znodes that respect vnode \( v \). Since a ZSDD is represented as a set of decomposition znodes, the set of \( Z[v] \)'s for all internal vnodes \( v \) can be seen as a ZSDD. The algorithm first calls rootState(), which returns the root vnode. The procedure depends on the types of subgraphs. The algorithm next calls construct(v, Z), which recursively construct child znodes of znodes respecting \( v \). If we naively construct znodes, the number of child znodes grows exponentially. We thus merge equivalent znodes during the construction of a ZSDD. Here, two znodes are equivalent if they respect the same vnode and represent the same family of sets. To detect equivalent znodes efficiently, we attach a label to each znode. The labels must be defined depending on the types of subgraphs so that two znodes are equivalent if they respect the same vnode and have the same label. We explain how to design labels in Section 4. The constructed ZSDD may have redundant znodes. Function reduce (\( Z \)) deletes such znodes.

Algorithm 2 shows function construct(v, Z). The function is called only for internal vnodes. In [19], the procedure of construct(v, Z) was designed depending on whether \( v^l \) is a leaf or not. Instead, we treat all internal vnodes in the same way, which makes it easy to design algorithms for several constraints. For each znode \( z \) in \( Z[v] \), the function calculates the prime-sub pairs corresponding to \( z \). We first initialize the set of prime-sub pairs elems to the empty set (Line 2). Function decomp(v, z) receives vnode \( v \) and znode \( z \) that respects \( v \), and returns the set of pairs of labels corresponding to the prime-sub pairs (Line 3). For each \( o \in \{l, r\} \), if \( v^o \) is a leaf vnode, we set vnode \( z^o \) to a terminal (Line 5). Function terminal(v, m) receives leaf vnode \( v \) and label \( m \), and returns an appropriate terminal depending on the types of subgraphs. If \( v^o \) is an internal vnode, we call unique(v, m, Z) (Line 6). The function receives vnode \( v \) and label \( m \), and checks whether \( Z[v] \) contains a znode with label \( m \). If such a znode exists, the function returns its address. Otherwise, the function creates a new znode that respects \( v \) and has label \( m \), stores it into \( Z[v] \), and returns its address. We add the prime-sub pair \((z^o, z^r)\) into elems (Line 7). After generating all the prime-sub pairs, we set elems as the child znodes of \( z \) (Line 8). Finally, for each \( o \in \{l, r\} \) such that \( v^o \) is an internal vnode, we call construct(v^o, Z) to recursively construct sub-ZSDDs (Lines 9–10).
The functions \( \text{reduce}(Z) \) and \( \text{unique}(v, m, Z) \) can be designed regardless of the types of subgraphs [19]. In contrast, the definition of labels and the procedures of \( \text{rootState}(v) \), \( \text{terminal}(v, m) \), and \( \text{decomp}(v, z) \) heavily depend on the types of subgraphs. To easily design them for several constraints, we relate a recursive formula for the desired set of subgraphs to top-down ZSDD construction. Intuitively, in our framework, internal vnodes correspond to recursion steps, while leaf vnodes correspond to base cases. Therefore, we only have to prove a recursive formula for the desired set of subgraphs. The recursive formula directly leads to the definition of labels and the procedures of subroutines. We can also show the correctness of the algorithm and the bound of the constructed ZSDD size from the recursive formula.

4 Subroutines for several constraints

We apply our framework to three fundamental constraints: the number of edges, degrees of vertices, and connectivity of vertices. By combining these constraints, we can specify several types of subgraphs. For each constraint, we show a recursive formula for the set of subgraphs satisfying the constraint. Using the recursive formula, we derive subroutines and bound the sizes of constructed ZSDDs. The proofs are omitted due to the space limitation.

4.1 Cardinality

Given graph \( G = (V, E) \), vtrees \( T \) whose leaves are labeled by the elements of \( E \), and non-negative integer \( k^* \), we construct a ZSDD that represents the family of sets with exactly \( k^* \) elements. We can also construct a ZSDD that represents the family of sets with at most or at least \( k^* \) elements (details are omitted). In the following, we focus on the “exactly \( k^* \)” constraint. For vnode \( v \), let \( E(v) \subseteq E \) be the set of graph edges that correspond to the leaf vnodes of the sub-vtree whose root is \( v \). For vnode \( v \) and non-negative integer \( k \), let \( f(v, k) \) be the family of subsets of \( E(v) \) with \( k \) elements, that is, \( f(v, k) = \{ S \mid S \subseteq E(v), |S| = k \} \). The desired family is \( f(v^\text{root}, k^*) \), where \( v^\text{Root} \) is the root vnode of \( T \). For leaf vnode \( v \), \( \ell(v) \) denotes the element corresponding to \( v \). We show a recursive formula for \( f(v, k) \).

\[ f(v, k) = \begin{cases} \{\emptyset\} & (k = 0) \\ \{\{\ell(v)\}\} & (k = 1) \\ \emptyset & \text{(otherwise)} \end{cases} \quad (4) \]

If \( v \) is internal, the following is an \((E(v^\ell), E(v^r))\)-partition:

\[ f(v, k) = \bigcup_{i=0}^{k} \left[ f(v^\ell, i) \cup f(v^r, k - i) \right]. \quad (5) \]

Using the recursive formula, we can design the subroutines of the framework. We use non-negative integers as znode labels. For znode \( z \) that respects vnode \( v \), the label of \( z \) indicates the number of elements that should be adopted from \( E(v) \). Function \( \text{rootState}(v) \) returns the root znode with label \( k^* \), since the desired family is \( f(v^\text{root}, k^*) \). Algorithm 3 shows the subroutines \( \text{terminal}(v, k) \) and \( \text{decomp}(v, z) \). \( \text{terminal}(v, k) \) is obtained from Equation (4). If \( k = 0 \), it returns \( z \) since \( \{\emptyset\} = \emptyset \) (Line 1). If \( k = 1 \), it returns \( \ell(v) \) since \( \{\{\ell(v)\}\} \) (Line 2). Otherwise, it returns \( \perp \) since \( \langle \perp \rangle = \emptyset \) (Line 3). Similarly, \( \text{decomp}(v, z) \) is obtained from Equation (5). The function initializes \( \text{elems} \) to the empty set (Line 4). Let \( k \) be the
Algorithm 3 Subroutines for the cardinality constraint.

Function : terminal(v, k)
1 if k = 0 then return ε
2 else if k = 1 then return ℓ(ν)
3 else return ⊥

Function : decomp(ν, z)
4 elems ← ∅
5 Let k be the label of z
6 for i ∈ [0, k] do
7   elems ← elems ∪ {(i, k − i)}
8 return elems

Figure 2 Intermediate ZSDDs for the cardinality constraint.

label of z (Line 5). If the prime has label 0 ≤ i ≤ k, then the sub has label k − i. Thus, we add the pair (i, k − i) to elems (Lines 6–7). Finally, we return elems (Line 8). The correctness of the algorithm directly follows from the correctness of Lemma 4.

Example 5. Let us construct a ZSDD that represents the family of subsets of \{A, B, C, D\} with exactly two elements. We use the vtree in Figure 1a. First, rootState() creates root znode \(z_1\) with label 2 and stores it into \(Z[v_1]\). The function then calls construct\((v_1, Z)\). \(Z[v_1]\) contains only one znode \(z_1\). Since \(z_1\) has label 2, decomp\((v_1, z_1)\) returns \{(0, 2), (1, 1), (2, 0)\}. The function first processes label pair \((0, 2)\). Since \(v'_1 = v_4\) is a leaf vnode, the function calls terminal\((v_4, 0)\), which returns \(ε\). Since \(v'_1 = v_2\) is not a leaf vnode, the function calls unique\((v_2, 2, Z)\). It creates new decomposition znode \(z_2\) that respects \(v_4\) and has label 2, stores it into \(Z[v_4]\), and returns its address. Similarly, for label pair \((1, 1)\), the corresponding prime-sub pair is calculated as \((B, z_2)\), where \(z_2\) is a new decomposition znode that respects \(v_2\) and has label 1. As for label pair \((2, 0)\), since the universe of the prime contains only one element, we discard this pair. As a result, the function set the prime-sub pairs \((ε, z_2)\) and \((B, z_3)\) as child nodes of \(z_1\). Figure 2a shows the current intermediate ZSDD. Since \(v'_1 = v_4\) is a leaf vnode and \(v'_1 = v_2\) is an internal vnode, the function calls only construct\((v_2, Z)\).

We go on to construct\((v_2, Z)\). \(Z[v_2]\) contains two znodes \(z_2\) and \(z_3\). The function processes \(z_2\) first. Since \(z_2\) has label 2, decomp\((v_2, z_2)\) returns \{(2, 0), (1, 1), (0, 2)\}. However, \((0, 2)\) is discarded because the universe of the sub only contains one element. As a result, the prime-sub pairs are calculated as \{(z_4, ε), (z_5, C)\}, where \(z_4\) and \(z_5\) are new decomposition znodes that respect \(v_3\). The labels of \(z_4\) and \(z_5\) are 2 and 1, respectively. The function processes \(z_3\) next. decomp\((v_2, z_3)\) returns \{(1, 0), (0, 1)\}. Here, znode \(z_5\) with label 1 already exists in \(Z[v_3]\), and thus unique\((v_3, 1, Z)\) returns \(z_5\). As a result, the set of prime-sub pairs is \{(z_5, ε), (z_6, C)\}, where \(z_6\) is a new znode that respects \(v_3\) and has label 0. Figure 2b shows the current intermediate ZSDD. Finally, construct\((v_3, Z)\) is called and Figure 2c shows the resulting ZSDD. By calling reduce\((Z)\), the ZSDD can be trimmed as Figure 1b.
Enumerating All Subgraphs Under Given Constraints Using ZSDDs

Using Lemma 4, we can also bound the size of the constructed ZSDD.

**Theorem 6.** If $\alpha$ is the ZSDD obtained by Algorithm 3, the size of $\alpha$ is $O(|E|k^2)$.

### 4.2 Degree

We denote a given degree constraint by function $\delta^*: V \rightarrow \mathbb{N}$, where $\mathbb{N}$ is the set of non-negative integers. For subgraph $S \subseteq E$, we say that $S$ satisfies $\delta^*$ if $\deg(S, u) = \delta^*(u)$ holds for all $u \in V$. For example, for the graph shown in Figure 3a and degree constraint $\delta^*$ such that $\delta^*(u_1) = \delta^*(u_4) = 1$ and $\delta^*(u_2) = \delta^*(u_3) = 2$, there are two subgraphs satisfying $\delta^*$ as shown in Figure 3b. Given $G$, $T$, and $\delta^*$, we construct a ZSDD representing the set of all subgraphs satisfying $\delta^*$. When a subgraph satisfies $\delta^*$, for every vertex $u$, the degree of $u$ in a subgraph must be “exactly” $\delta^*(u)$. Although we mainly discuss this “exact” constraint, we can easily modify the algorithm to deal with “at most” or “at least” constraints.

Similarly to Lemma 4, we show a recursive formula for the set of subgraphs satisfying the degree constraint. For vnode $v$, $V(v)$ denotes the set of vertices to which an edge in $E(v)$ is incident. Let us consider a degree constraint whose domain is limited to $\delta: V(v) \rightarrow \mathbb{N}$. We define $f(v, \delta)$ as the set of subgraphs of $V(v)$ such that, for all $u \in V(v)$ and $S \in f(v, \delta)$, degree $\deg(S, u)$ equals $\delta(u)$. We show a recursive formula for $f(v, \delta)$.

**Lemma 7.** Let $v$ be a vnode, and $\delta$ be a function from $V(v)$ to $\mathbb{N}$. If $v$ is a leaf vnode, let $u_1$ and $u_2$ be the endpoints of graph edge $\ell(v)$. Then, the following hold:

$$f(v, \delta) = \begin{cases} \{\emptyset\} & (\delta(u_1) = \delta(u_2) = 0) \\ \{\{\ell(v)\}\} & (\delta(u_1) = \delta(u_2) = 1) \\ \emptyset & \text{(otherwise)} \end{cases}$$  \hspace{1cm} (6)

If $v$ is internal, the following is an $(E(v^l), E(v^r))$-partition:

$$f(v, \delta) = \bigcup_{(\delta^l, \delta^r) \in P(v, \delta)} [f(v^l, \delta^l) \sqcup f(v^r, \delta^r)],$$  \hspace{1cm} (7)

where $P(v, \delta)$ is the set of pairs of functions $\delta^l: V(v^l) \rightarrow \mathbb{N}$ and $\delta^r: V(v^r) \rightarrow \mathbb{N}$ such that

1. $\forall u \in V(v^l) \cap V(v^r), \; \delta^l(u) + \delta^r(u) = \delta(u),$  \hspace{1cm} (8)
2. $\forall u \in V(v^l) \setminus V(v^r), \; \delta^l(u) = \delta(u),$  \hspace{1cm} (9)
3. $\forall u \in V(v^r) \setminus V(v^l), \; \delta^r(u) = \delta(u).$  \hspace{1cm} (10)

For vnode $v$, the frontier of $v$ is $F(v) = V(v^l) \cap V(v^r)$. Let us consider the graph shown in Figure 3a and the degree constraint $\delta^*$, which we defined above. For vnode $v$, let $E(v^l) = \{A, B, C\}$ and $E(v^r) = \{D, E\}$. It follows that $F(v) = \{u_2, u_3\}$. Figure 4a shows the current situation. The set of red (solid) and blue (dashed) edges are $E(v^l)$ and $E(v^r)$,
respectively. The set of vertices in the shaded area is $F(v)$. We can interpret Equations (7) to (10) as follows. For vertex $u \in V(v') \setminus V(v)$, $\delta(u)$ edges in $E(v')$ must be incident to $u$, and thus $\delta'(u) = \delta(u)$ (Equation (9)). A similar statement holds for vertices in $V(v') \setminus V(v'')$ (Equation (10)). The remaining vertices are in $F(v)$. For vertex $u \in F(v)$, both edges in $E(v')$ and $E(v'')$ are incident to $u$. Here, we guess how many edges in $E(v')$ are incident to $u$. This results in generating nine prime-sub pairs, as shown in Figure 4b. We can construct the ZSDD by recursively applying Lemma 7. Here we use $\delta$ as a label of a znode.

Let us analyze the sizes of ZSDDs constructed by our algorithm. The width of a vtree is $\max_{v \in \text{in}(T)} V(v') \cap V(v'')$, where $\text{in}(T)$ is the set of internal vnodes.

\begin{theorem}
If $\alpha$ is the ZSDD representing $f(v_{\text{root}}, \delta^*)$ obtained by our algorithm, the size of $\alpha$ is $O(|E|d^{2W})$, where $d = \max_{u \in V} \delta^*(u) + 1$ and $W$ is the width of the input vtree.
\end{theorem}

There exists a vtree whose width equals the branch-width of the graph [19]. Given such a vtree, the ZSDD size is $O(|E|d^{2bw}(G))$, where $bw(G)$ is the branch-width of $G$.

### 4.3 Spanning tree

We construct a ZSDD representing the set of all spanning trees of $G$. With a few modifications, we can also construct a ZSDD representing the set of all connected subgraphs. We introduce some notation. If vertices $u, u'$ are connected in subgraph $S \subseteq E$, we write $u \sim u'$. Note that $\sim$ is an equivalence relation on $V$; an equivalence class (a set of vertices) is a connected component of $S$. Two vertex subsets $C, C' \subseteq V$ are connected if there exist $u \in C$ and $u' \in C'$ with $u \sim u'$; we write this as $C \sim C'$. We also write $u \sim C'$ if $C \sim C'$ for $C = \{u\}$.

For vnode $v$, let $C$ be a partition of vertex set $F(v)$, that is, $C = \{C_1, \ldots, C_g\}$ where $C_i \subseteq F(v)$ is a vertex set satisfying $C_i \cap C_j = \emptyset$ for $i \neq j$ and $\bigcup_{i=1}^{g} C_i = F(v)$. Let $\mathcal{R} = \{R_1, \ldots, R_n\}$ be a disjoint set family defined over vertex sets in $C$, that is, $R_i \subseteq C$ and $R_i \cap R_j = \emptyset$ for all $i \neq j$. Let $U(\mathcal{R}) = \{C \mid \exists i : C \in R_i\}$. Function $\text{Same}(\mathcal{R}, C, C')$ returns true if there exists $R_i \in \mathcal{R}$ such that $C, C' \in R_i$, otherwise false. To represent the set of all spanning trees, we define $f(v, C, \mathcal{R})$ as the set of subgraphs $S \subseteq E(v)$ satisfying the following:

- for every $C_1, C_2 \in U(\mathcal{R})$, $C_1 \not\sim C_2$ holds if and only if $\text{Same}(\mathcal{R}, C_1, C_2) = \text{true}$,
- for every $C \in C \setminus U(\mathcal{R})$, there exists a unique $C' \in U(\mathcal{R})$ such that $C \not\sim C'$. Similarly, for every $u \in V(v) \setminus F(v)$, there exists a unique $C' \in U(\mathcal{R})$ such that $u \not\sim C'$, and $S$ does not contain a cycle.

Intuitively, $C$ represents the sets of equivalent vertices. That is, vertices in the same vertex group $C \in C$ are regarded to be connected. $\mathcal{R}$ represents the connectivity constraints over such equivalent sets of vertices. The first condition above requires that two vertex subsets $C$ and $C'$ must be connected in $S$ if and only if they appear in the same $R \in \mathcal{R}$. The second condition requires that, every equivalent vertex subset appearing in $V(v)$ but does not appear in $\mathcal{R}$ must be connected to a vertex subset $C'$ appearing in $\mathcal{R}$. The third condition requires that, for every vertex subset $C$ appearing in $V(v)$ but does not appear in $\mathcal{R}$, it must be connected to a vertex subset $C'$ appearing in $\mathcal{R}$.
9:10 Enumerating All Subgraphs Under Given Constraints Using ZSDDs

Algorithm 4 Subroutines for spanning trees.

Function \(\text{terminal}(v, (C, R))\)

1. Let \(u_1\) and \(u_2\) be the endpoints of the graph edge \(\ell(v)\).
2. if \(\text{Same}(C, u_1, u_2) = \text{true}\) then
   3. Let \(C \in \mathcal{C}\) be the set containing \(u_1\) and \(u_2\).
   4. if \(C \in U(R)\) then return \(\varepsilon\) else return \(\perp\).
   5. else
   6. Let \(C_1, C_2 \in \mathcal{C}\) be the sets containing \(u_1\) and \(u_2\), respectively.
   7. if \(\text{neither } C_1 \text{ nor } C_2 \text{ is in } U(R)\) then return \(\perp\).
   8. else if exactly one of \(C_1\) or \(C_2\) is in \(U(R)\) then return \(\ell(v)\).
   9. else
   10. if \(\text{Same}(R, C_1, C_2) = \text{true}\) then return \(\ell(v)\) else return \(\varepsilon\).

Function \(\text{decomp}(v, z)\)

11. \(\text{elems} \leftarrow \emptyset\)
12. Let \((C, R)\) be the label of \(z\).
13. \(\mathcal{C}' \leftarrow \{C \cap F(v') \mid C \in \mathcal{C}, \mathcal{C} \cap F(v') \neq \emptyset\} \cup \{\{u\} \mid u \in F(v') \setminus F(v)\}\)
14. for \(R' \in \text{enumPartition}(\mathcal{C}')\) do
15.   if \(\text{isCompatible}(C, R, R') = \text{true}\) then
16.     \(C^*, R^* \leftarrow \text{calcSubState}(C, R, R')\)
17.     \(\text{elems} \leftarrow \text{elems} \cup \{((C', R'), (C^*, R^*))\}\)

Condition is for acyclicity. The set of all spanning trees of \(G\) is \(f(v^{\text{root}}, C^*, R^*)\), where \(C^* = \{\{u\} \mid u \in F(v^{\text{root}})\}\) and \(R^* = \{\{C\}\}\) for an arbitrary \(C \in C^*\) since initially there are no equivalent vertices and all vertices must be connected to form a spanning tree.

Unfortunately, it is quite complicated to show a recursive formula for \(f(v, C, R)\) and prove it theoretically. Thus, we show pseudo-code of subroutines and explain the behavior using an example. We use \((C, R)\) as a nodal label. \(\text{rootState}(C, R)\) returns the root node label \((C^*, R^*)\). Algorithm 4 shows functions \(\text{terminal}(v, (C, R))\) and \(\text{decomp}(v, z)\). \(\text{terminal}(v, (C, R))\) returns an appropriate terminal with respect to the label of \(z\). Let \(u_1\) and \(u_2\) be the endpoints of the edge \(\ell(v)\). We first consider the case that \(u_1\) and \(u_2\) are contained in a vertex group \(C\in\mathcal{C}\) (Lines 2–4). If \(C \not\in U(R)\), \(C\) must be connected to some \(C' \in U(R)\). However, now we have \(C = \{C\}\), and thus there is no such \(C'\). Therefore, we return \(\perp\). If \(C \in U(R)\), to avoid generating a cycle, we must not adopt edge \(\ell(v)\). Thus we return \(\varepsilon\). We next consider the case that \(u_1\) and \(u_2\) are contained in different sets \(C_1, C_2 \in \mathcal{C}\) (Lines 5–10). If neither \(C_1\) nor \(C_2\) appear in constraints \(R\), they must be connected to some \(C' \in U(R)\), but there are no such \(C'\). Thus we return \(\perp\) (Line 7). If either of \(C_1\) or \(C_2\) appears in \(R\), the unconstrained one must be connected with the other one, which has a constraint in \(R\). Thus we return \(\ell(v)\) (Line 8). If both \(C_1\) and \(C_2\) appear in \(R\), we return the corresponding terminal depending on whether they appear in the same \(R_i \in R\) or not. If so, edge \(\ell(v)\) must be adopted, and thus we return \(\ell(v)\). Otherwise, the edge must not be adopted, and thus we return \(\varepsilon\) (Lines 9–10).

We go on to \(\text{decomp}(v, z)\). We first enumerate all possible sets of constraints \(R_i\) of the prime. Since \(R_i\) is a partition of vertex groups \(C\), function \(\text{enumPartition}(C')\) enumerates all partitions of \(C'\). There may be partitions of \(C'\) that are not compatible with \((C, R)\); if \(C_1 \in R_i \text{ and } C_2 \in R_j\) for \(R_i, R_j \in R\) where \(i \neq j\), they must not appear in the same \(R \in R_i\). In addition, for every constraint \(R \in R_i\), a vertex in \(F(v_i)\) must appear in some \(C \in R\) in order to obtain a spanning tree. If both conditions are satisfied, \(R_i\) is compatible with \((C, R)\). Function \(\text{isCompatible}(C, R, R_i)\) returns \(\text{true}\) if \(R_i\) is compatible with \((C, R)\),
We conduct experiments to evaluate the performance of the proposed top-down construction algorithm for ZSDDs in the same way as an existing paper [19]. The vtrees for ZSDDs are obtained by a practical algorithm to find a branch decomposition with a small width [6]. To implement the top-down algorithm for ZSDDs, we use the top-down algorithm for ZSDDs with a limitation that vtrees must be right-linear. Here, a vtree is right-linear if, for every internal vnode, its left child is a leaf. Since there is a one-to-one correspondence between ZDDs with ZSDDs using right-linear vtrees, by inputting right-linear vtrees, we can simulate ZDD construction. We use two element orders for ZDDs. The first one uses the order obtained by a breadth-first traversal of input graphs, as is used in graphillion [9], a library that implements a top-down construction algorithm for ZDDs. The other one uses the order induced from the vtrees used in the proposed method. Here we say an order is induced if a left-right traversal of a vtree gives the visiting order of variables [22]. We use the benchmark graphs of [19]: TSPLIB and RomeGraph. We constructed ZSDDs representing two types of subgraphs: 1) maximum degree at most two and 2) spanning trees. All code was written in C++ and compiled by g++-5.4.0 with -O3 option. All experiments were conducted on a machine with Intel Xeon W-2133 3.60 GHz CPU and 256 GB RAM.

5 Experiments

As discussed in Section 4.2, there exists a vtree whose width equals the branch-width of the graph. Given such a vtree, the size of a constructed ZSDD is \( \mathcal{O}(|E|^{3bw(G)}) \).

Tables 1 and 2 show the results. In the tables, TD means the proposed method. Z(b) and Z(v) indicate top-down methods for ZDDs that employ breadth-first ordering and vtree traversing ordering, respectively. The empty fields indicate failure to complete within 600 seconds. We omit the instances for which all the methods finished within a second and at most one method finished within 600 seconds. In almost all cases, TD ran fastest and the sizes of ZSDDs are smaller than those of ZDDs. For example, for spanning trees (Table 2), the time of TD is up to 7898 times faster than Z(b), and 188 times faster than Z(v). The size of TD is up to 476 times smaller than Z(b) and 73 times smaller than Z(v). These results show the efficiency of our method. Using constructed ZDDs and ZSDDs, we can also enumerate subgraphs explicitly in polynomial time per subgraph [15, 18].

### Concluding remarks

We have proposed a novel framework of algorithms for top-down ZSDD construction. We have shown the solid subroutines for three fundamental constraints: the number of edges, degree of vertices, and connectivity of vertices. We have shown the sizes of constructed ZSDDs can be bounded by the branch-width of the input graph. Experiments confirmed the efficiency of our method. Using Apply operations, we can combine several constraints. For example, we can extract connected subgraphs from ZSDD \( \alpha \) by constructing ZSDD \( \beta \) representing the set of all connected subgraphs and computing \( \alpha \cap \beta \). We believe that our framework can be used to solve various real-world problems.
